Most turbines have either two or three blades. Wind blowing over the blades causes the blades to "lift" and rotate.

Kinetic energy is the energy of motion, and in the case of a wind turbine, it is the energy associated with the blades spinning due to the force of the wind. For example, as wind speeds increase, the blades ...

When wind flows across the blade, the air pressure on one side of the blade decreases. The difference in air pressure across the two sides of the blade creates both lift and drag. The force of the lift is ...

Pitch: Blades are turned, or pitched, out of the wind to keep the rotor from turning in winds that are too high or too low to produce electricity. Rotor: The blades and the hub together are called ...

In this video, we break down the science behind wind turbine blade rotation . Learn how wind forces cause the blades to spin, the role of airfoil design, and how turbines efficiently...

Below, we are going to analyse the 10 most relevant terms in onshore wind energy to find out, for example, what a nacelle is or what the function of a gearbox is. This is perhaps the main word in the ...

An airfoil is the aerodynamic cross-sectional profile of the blade, and is designed to convert the downwind drag force of a wind stream into a right-angled lifting force that causes the blades to rotate.

Here's how I described the book in a promotional release. "From HAWT to VAWT and from Anemometer to Zephyr, the glossary offers a sometimes irreverent description of the words that ...
