What is welding deformation?

Welding deformation refers to the phenomenon where the shape and size of the welded workpiece change due to uneven heat input and output during the welding process.

Does welding heat input affect welding deformation?

This study examines the impact of welding heat input on the residual stress and welding deformation of large, thin-walled constructions made of ultra-high strength steel using a single shot calculation method. These structures are susceptible to warpage distortion after welding, which negatively affects production precision.

How does welding deformation affect a welded workpiece?

Reduced Load-Bearing Capacity: Welding deformation changes the geometric dimensions of welded workpieces, altering their stress states and affecting their ability to withstand loads.

Can we predict Weld deformation in thin plate ultra-high strength steel (UHSS) structures?

Therefore, predicting and minimizing weld deformation in thin plate ultra-high strength steel (UHSS) structures is critical. Quantitative prediction of welding residual stress and deformation trends can enhance manufacturing precision and serviceability.

Can welding deformation be integrated into the fatigue life calculation process? To address this gap, this paper proposes integrating welding deformation into the fatigue life calculation process for welded ...
